# Relax Inc. | User Adoption: Findings

**Question:** Which factors are associated with adoption, and can signup attributes predict it?

**Definition and approach.** An adopted user logged in on at least three distinct calendar days within any seven-day window. I deduplicated daily logins and scanned chronological visits for a qualifying three-visit window. All 12,000 users were included in the retrospective analysis; 1,602 (13.35%) qualified.

| Account creation source | Users | Adopted | Adoption rate |
|---|---|---|---|
| Google authentication | 1,385 | 232 | 16.75% |
| Guest invite | 2,163 | 360 | 16.64% |
| Website signup | 2,087 | 293 | 14.04% |
| Organization invite | 4,254 | 553 | 13.00% |
| Personal projects | 2,111 | 164 | 7.77% |

**Key findings.** Signup source shows the largest practical differences: Google-auth and guest-invited users adopt at more than twice the rate of personal-project users. Invited users overall show 14.23% adoption versus 12.34% without a recorded inviter, but this overlaps with creation source. Mailing-list opt-in (13.83% vs 13.19%) and marketing drip (13.73% vs 13.28%) have small unadjusted differences; these do not establish marketing effectiveness.

**Forward-looking check.** To avoid confusing lifetime adoption with future prediction, I separately predicted adoption during the first 14 days after signup, using only signup-related fields and an 80/20 chronological train/test split. Among 11,679 users with sufficient observation, 235 (2.01%) adopted within 14 days. A logistic regression achieved test ROC-AUC **0.535** and PR-AUC **0.0275** (test prevalence **0.0193**). This is weak predictive discrimination; the associations are more useful for prioritizing research than deploying a targeting model.

**Recommendations.** Investigate onboarding friction for personal-project invitations, compare guest-invite and Google-auth flows, and measure early activation events (first project created, collaborator added, first task completed). Test onboarding changes through randomized experiments rather than assuming observed associations are causal.

**Limitations and further work.** Current user attributes may not reflect signup-time values; exact changes to marketing and invitation status are unavailable. Cohort exposure varies; the 14-day outcome mitigates this but is rare. Analyze cohort-adjusted conversion, organization-level clustering, product events, invitation acceptance, retention, and adoption at 30/60 days. The supplied data do not establish causation.
